(Received 27 January 2015; accepted 12 March 2015)

We investigate the behavior of an ensemble of $N$ non-interacting, identical atoms excited by a laser. In general, the $i$-th atom sees a Rabi frequency $\Omega_i$, an initial position dependent laser phase $\phi_i$, and a motion induced Doppler shift of $\delta_i$. When $\Omega_i$ or $\delta_i$ is distinct for each atom, the system evolves into a superposition of $2^N$ intercoupled states, of which there are $N + 1$ symmetric and $(2^N - (N + 1))$ asymmetric collective states. For a collective state atomic interferometer (COSAIN), we recently proposed, it is important to understand the behavior of all the collective states under various conditions. In this paper, we show how to formulate the properties of these states under various non-idealities, and use this formulation to understand the dynamics thereof. We also consider the effect of treating the center of mass degree of freedom of the atoms quantum mechanically on the description of the collective states, illustrating that it is indeed possible to construct a generalized collective state, as needed for the COSAIN, when each atom is assumed to be in a localized wave packet. The analysis presented in this paper is important for understanding the dynamics of the COSAIN, and will help advance the analysis and optimization of spin squeezing in the presence of practically unavoidable non-idealities as well as in the domain where the center of mass motion of the atoms is quantized.

Keywords: atomic ensembles; symmetric collective states; asymmetric collective states; atomic interferometer

1. Introduction

Atom interferometry is emerging as a very important avenue of precision metrology. It has been used as a gyroscope [1–3] as well as an accelerometer [4,5]. It has also been used for accurate measurements of gravity [6,7], gradients in gravity [8], as well as gravitational red-shift [9]. Other applications include measurement of fine structure constants [10–12], as well as the realization of a matter-wave clock [12]. The rotation sensitivity of an atom interferometric gyroscope (AIG) is due to the phase difference between two paths arising from the Sagnac effect [13–15]. This phase difference is proportional to the area enclosed by the interferometer as well as the mass of each atom.

Motivated by this mass dependence of the rotation sensitivity of an AIG, we have recently proposed an interferometer that exploits the collective excitation of an ensemble of atoms [16]. To explain the principle behind this briefly, we consider an assembly of $N$ non-interacting identical two-level atoms, as illustrated in Figure 1(a). For a practical atomic interferometer, these levels are actually metastable hyperfine ground levels, coupled to an intermediate state via off-resonant counter-propagating optical fields. However, the basic concept can be illustrated by considering these two states to be coupled by a single, traveling laser field [17]. The atoms are initially prepared in quantum state $|g, 0\rangle$ and $|e, \hbar k\rangle$, with the amplitude of each state depending on the intensity of the laser beam, $\Omega$, and the time of interaction, $t$.

In a single atom interferometer, a two-level atom is first split into an equal superposition of $|g, 0\rangle$ and $|e, \hbar k\rangle$ by a $\pi/2$-pulse, and then inverted by a $\pi$-pulse. At the end of another free drift time, $T$, the two paths are recombined by another $\pi/2$-pulse. This is shown schematically in Figure 1(b). A possible phase difference, $\Delta\phi$, between the two paths manifests itself in the amplitude of the states at the end of the $\pi/2 - \pi - \pi/2$ sequence. For example, the amplitude of $|g\rangle$ at the end of the interferometric sequence varies as $\cos^2(\Delta\phi/2)$ [1,14]. It is also possible to make a similar interferometer using only a single zone excitation [18,19].

We have shown in Ref. [16] how an ensemble of \( N \) atoms can be used to make a Collective State Atomic Interferometer (COSAIN) which also makes use of the \( \pi/2 - \pi - \pi/2 \) pulse sequence employing counter-propagating Raman excitations in a \( \Lambda \) system, but has properties that differ very significantly from the Conventional Raman Atomic Interferometer (CRAIN) employing the same pulse sequence. For example, the width of the fringes generated as a function of the differential phase between the two paths (or, equivalently, a rotation applied perpendicular to its plane) is reduced by a factor of \( \sqrt{N} \), when compared to the same for the CRAIN. The minimum measurable phase shift, under quantum noise limited (QNL) operation, is given by 

\[
\Delta \phi_{c}^{QNL} = \frac{\pi}{\sqrt{N} \tau \eta c},
\]

where \( n \) is the number of interrogations per unit time, \( \tau \) is the total observation time, and \( \eta c \) is the quantum efficiency of detecting one of the collective states. This is to be compared with the same for a CRAIN, which is given by 

\[
\Delta \phi_{c}^{QNL} = \frac{\pi}{\sqrt{m} \tau \eta c},
\]

where \( m \) is the flux of atoms per unit time, and \( \eta c \) is the quantum efficiency of detecting each atom. For comparison, we consider a situation where \( m = N \eta c \). Thus, \( \Delta \phi_{c}^{QNL} \) can be substantially smaller than \( \Delta \phi_{c}^{QNL} \), since \( \eta c \) can be very close to unity, while \( \eta c \) is generally very small because of geometric constraints encountered in collecting fluorescence from the atoms [16]. In order to understand the basic principles of operation of such an interferometer, it is instructive to recall first the Dicke states [20–22].

![Figure 1](image1.png)

Figure 1. (a) Ensemble of \( N \) two-level atoms in a classical laser field propagating the \( z \)-direction, (b) a single atom interferometer produced via \( \pi/2 - \pi - \pi/2 \) sequence of excitation.

In Ref. [20], Dicke showed that for a dilute ensemble of \( N \) atoms where the atoms do not interact, the ensemble evolves to a superposition of \( N+1 \) symmetric states (shown in Figure 2). Some of the possible Dicke states are defined as follows

\[
|G\rangle = |g_1, g_2, \ldots, g_N\rangle,
\]

\[
|E_{N}\rangle = \sum_{i=1}^{N} |g_{i}, g_{2}, \ldots, g_{N}\rangle / \sqrt{N},
\]

\[
|E_{N-1}\rangle = \sum_{i=1}^{N} |g_{1}, g_{2}, \ldots, g_{i-1}, g_{i+1}, \ldots, g_{N}\rangle / \sqrt{N},
\]

\[
|E_{N-2}\rangle = \sum_{i=1}^{N} |g_{1}, g_{2}, \ldots, g_{i}, g_{i+2}, \ldots, g_{N}\rangle / \sqrt{N},
\]

etc. where \( \binom{N}{n} = \frac{N!}{n!(N-n)!} \).

A COSAIN is configured essentially the same way as the CRAIN with two exceptions. First, it must make use of trapped atoms, released sequentially to the interferometer. Second, the detection process is designed to measure the probability of finding all the atoms in one of the collective states, such as \( |G\rangle \). The reduction in the width of the fringe occurs due to a combination of the interferences among all the collective states, which follow different paths. Details of this process can be found in Ref. [16]. We have also shown how a Collective State Atomic Clock (COSAC) can be realized in this way, also with a \( \sqrt{N} \) reduction in the width of the fringes [23]. Just as the COSAIN is a variant of the CRAIN, the COSAC is a variant of the Conventional Raman Atomic Clock (CORAC) [24–27]. In Ref. [23], we show how a conventional microwave clock [28,29] can also be converted into a COSAC.

As noted above, the COSAIN makes use of counterpropagating Raman transitions. As such, the characteristic wave number is \( k \), where \( k = (k_1 + k_2) \), and \( k_1 \) and \( k_2 \) are the wave numbers of the two laser beams. The non-zero temperature of a MOT provides a spread in the velocity of the constituent atoms. Therefore, each atom in the ensemble experiences a Doppler shift leading to a spread in detuning, with a zero mean value. Due to the finite size of the ensemble, each atom may experience a slightly different Rabi frequency depending on the spatial variation.
in the intensity profile of the laser beam. These factors contribute to a complex picture of an ensemble in a practical experiment. Furthermore, a semiclassical treatment of a quantum mechanical problem is not adequate. The wave packet nature of the atoms must also be taken into account by considering the center of mass (COM) momentum of the atomic states.

In this paper, we present a description of collective states under generalized and non-ideal conditions, including a situation where the motion of the COM of each atom is treated quantum mechanically. Such a comprehensive model of the collective states currently does not exist in the literature, and is important for understanding the behavior of the COSAIN. This comprehensive model of collective states, including the case where the COM motion is quantized, is assumed to be resonant for stationary atoms. Each atom, \( i \), depending on its velocity. The Rabi frequency, \( \Omega_i \), experienced by the \( i \)-th atom depends on its position.

The laser field is assumed, arbitrarily, to be polarized in the \( x \) direction. In the laboratory frame, the electric field at any point \( \mathbf{r} = x \hat{x} + y \hat{y} + z \hat{z} \), defined arbitrarily with respect to an origin, can be expressed as \( \mathbf{E}_i(\mathbf{r}, t) = \tilde{x} E_0 \exp[-(x^2 + y^2)/2\sigma_L^2]\cos(\omega_0 t - k z) \), where \( \sigma_L \) represents the width of the laser beam in the transverse directions. Assume now that, at \( t = 0 \), the \( i \)-th atom is positioned at \( \mathbf{r}_0 = x_0 \hat{x} + y_0 \hat{y} + z_0 \hat{z} \), and is moving at a velocity \( \mathbf{v}_i = v_{ix} \hat{x} + v_{iy} \hat{y} + v_{iz} \hat{z} \). We ignore for now any change to this velocity due to the interaction with the laser field. This issue will be addressed later when we consider the motion of the COM of the atom quantum mechanically. In the reference frame of this atom, which is defined by the vector \( \mathbf{r}_i = \mathbf{r}_0 + \mathbf{v}_i t \), the electric field can be expressed as \( \mathbf{E}_i(\mathbf{r}_i, t) = \tilde{x} E_0 \exp[-((x_{0i} + v_{ix} t)^2 + (y_{0i} + v_{iy} t)^2)/2\sigma_L^2]\cos(\omega_0 t - k (x_{0i} + v_{ix} t)) \). The transverse motion of the atom will lead to a time-dependent variation of the amplitude of the Rabi frequency. We assume that, for typical systems of interest, \( v_{ix} t \ll \sigma_L \) and \( v_{iy} t \ll \sigma_L \), so that this variation can be ignored. We can then write the field seen by the atom in its reference frame as \( \mathbf{E}_i(\mathbf{r}, t) = \tilde{x} E_0 \exp[-(x_{0i}^2 + y_{0i}^2)/2\sigma_L^2]\cos(\omega_0 t - \xi_i) \), where \( \omega_0 = \omega_0 - kv_{iz} \) is the Doppler shifted frequency seen by the atom, and \( \xi_i = k z_{0i} \) is a reference phase relation, determined by the initial position of the atom, between the atom and the field for all values of \( t \).

In the electric dipole approximation, the Hamiltonian for the \( i \)-th atom can be written as \( H_i = P_i^2/2m + H_{0i} + q \rho_i \mathbf{E}_i \), where \( P_i \) is the COM momentum in the \( z \)-direction, \( H_{0i} \) is the internal energy of the atom, \( \rho_i \) is the position of the electron with respect to the nucleus, \( q \) is the electronic charge, and \( m \) is the mass of the atom. As mentioned above, we are treating the motion of the COM of the atom semiclassically, deferring the quantum mechanical model thereof to a later part of this paper. As such, the COM term in the Hamiltonian can be ignored. Upon making the rotating-wave approximation, \( H_i \) can then be expressed in the bases of \( |g_i\rangle \) and \( |e_i\rangle \) as:

\[
H_i/\hbar = \omega_e |g_i\rangle \langle g_i| + \omega_e |e_i\rangle \langle e_i| + \Omega_i (\exp(i (\omega_0 t - \xi_i)) |g_i\rangle \langle e_i| + h.c.)/2, \tag{2}
\]

where \( \Omega_i \equiv |g_i\rangle \langle x \cdot \rho_i| e_i\rangle E_i/\hbar = |e_i\rangle \langle x \cdot \rho_i| |g_i\rangle E_i/\hbar \).

The state of this atom, \( |\psi_i\rangle \), evolves according to the Schrödinger equation, \( i\hbar \partial |\psi_i\rangle / \partial t = H_i |\psi_i\rangle \). We define a transformed state vector \( |\psi'_i\rangle = Q_i |\psi_i\rangle \), where \( Q_i \) is the unitary transformation, defined as

\[
Q_i = \sum_{j=1}^{2} \exp(i (a_{ij} t + b_{ij})) |j\rangle \langle j|, \tag{3}
\]

where \( a_{ij} \) and \( b_{ij} \) are the arbitrary parameters. The Hamiltonian for this state vector is then \( H'_i = Q_i H_i Q_i^{-1} = \hbar Q_i Q_i^{-1} \), so that \( i\hbar \partial |\psi'_i\rangle / \partial t = H'_i |\psi'_i\rangle \). To render \( H'_i \)
time independent, we set \( a_{11} = \omega_g \) and \( a_{12} = \omega_{hi} + \omega_g \).

Now, setting \( b_{11} = 0, b_{22} = -\xi_1 \) makes \( H'_R \) independent of any phase factor as well. In this frame, the \( Q \)-transformed Hamiltonian thus becomes

\[
H'_Q = -\delta_i |e'_i\rangle \langle e'_i| + \Omega_i (|g'_i\rangle \langle g'_i| + h.c.)/2. \quad (4)
\]

The new basis vectors, \(|g'_i\rangle\) and \(|e'_i\rangle\), are related to the original basis vectors as \( \exp(-i\omega_{hi} t) |g_i\rangle \) and \( \exp(-i(\omega_e + \delta_i) t - \xi_i)) \langle e_i| \), respectively. Assuming that the \( i \)-th atom is initially in the state \( c_g(t = 0) |g'_i\rangle + c_e(t = 0) |e'_i\rangle \), its quantum state can be written as

\[
|\psi'_i\rangle = \exp(i\delta_i t/2) \left( c_g(0) \cos \left( \frac{\Omega_i t}{2} \right) - i c_g(0) \delta_i + c_e(0) \Omega_i \sin \left( \frac{\Omega_i t}{2} \right) \right) |g'_i\rangle
+ \left( -i c_g(0) \Omega_i - c_e(0) \delta_i \right) \sin \left( \frac{\Omega_i t}{2} \right) |e'_i\rangle
+ c_e(0) \cos \left( \frac{\Omega_i t}{2} \right) |e'_i\rangle, \quad (5)
\]

where \( \Omega'_i = \sqrt{\Omega^2_i + \delta^2_i} \) is the effective coupling frequency of this atom.

Since we assume no interaction among the atoms, the ensemble Hamiltonian is the sum of all the individual Hamiltonians corresponding to each atom in the ensemble, \( H'_E = \sum_i H'_i. \) The state of the ensemble, therefore, evolves according to the Schrödinger equation, \( i\hbar \partial_t |\psi'_E\rangle / \partial t = H'_C |\psi'_E\rangle. \) For illustrative purposes, as well as transparency, let us consider first the case of \( N = 2 \). \( H'_C \) can be expressed as \( H'_C \otimes I_2 + I'_C \otimes H'_2 \), where \( I'_C \) is the identity operator in the basis of \(|g'_1\rangle\) and \(|e'_1\rangle\) for the \( i \)-th atom. For instance,

\[
|g'_1 g'_2\rangle H'_C |g'_1 e'_2\rangle = |g'_1 H'_1 |g'_1 I'_1 |e'_2\rangle + |g'_1 I'_2 |g'_1 e'_2\rangle
\]

\[
|g'_2 H'_2 |g'_2 e'_2\rangle = |g'_2 H'_1 |g'_2 e'_2\rangle + |g'_2 I'_2 |g'_2 e'_2\rangle = h\Omega'_2/2. \quad (6)
\]

Consider first the case where all the Rabi frequencies are the same, and there are no detunings. The \( Q \)-transformed Hamiltonian for each atom is then formally identical, since the phase factors due to different positions are encoded in the transformed basis states \(|g'_i\rangle\) and \(|e'_i\rangle\). Thus, the coupled collective states would now be formally identical to the symmetric Dicke states. For example,

\[
|G'\rangle = |g'_1\rangle |g'_2\rangle,
|E'_1\rangle = (|g'_1 e'_2\rangle + |g'_2 e'_1\rangle) / \sqrt{2},
|E'_2\rangle = |e'_1\rangle |e'_2\rangle. \quad (7)
\]

It should be noted that each of the constituent individual atomic states in these expressions include the temporal and spatial phase factors. Thus, these states behave the same way as the conventional Dicke symmetric collective states, independent of the distance between the two atoms. It should also be noted that there exists another collective state, \(|E'_{1,1}\rangle \equiv (|g'_1 e'_1\rangle - |e'_1 g'_1\rangle) / \sqrt{2} \) which remains fully uncoupled from the symmetric set. The states \(|E'_1\rangle\) and \(|E'_{1,1}\rangle\) result from a \( \pi/4 \) rotation in the Hilbert subspace spanned by \(|e'_1 g'_2\rangle\) and \(|g'_1 e'_2\rangle\), as illustrated in Figure 3(a).

Consider next the case where there is still no detuning, but the Rabi frequencies are unequal. It is not obvious what the form of the symmetric collective states should be in this case. Consider first the task of finding the first excited symmetric collective state (SCS). Since the \(|G'\rangle\) state will, by definition, be coupled only to this state, we can define this state, in general, as

\[
|E'_1\rangle = \frac{H'_C |G'\rangle}{\sqrt{|G'|H'_C |G'\rangle}}. \quad (8)
\]

where the denominator ensures that this state is normalized.

When applied to the particular case at hand, we thus get \(|E'_1\rangle = \Omega_1 |e'_1 g'_2\rangle + \Omega_2 |g'_1 e'_2\rangle) / \sqrt{\Omega^2_1 + \Omega^2_2} \). A rotation operator, \( R \), rotates the Hilbert subspace, \( \Phi_{2,1} \), formed by \(|e'_1 g'_2\rangle\) and \(|g'_1 e'_2\rangle\) by an angle \( \theta = \tan^{-1}(\Omega_1 / \Omega_2) \), such that one of the resulting states is \(|E'_{1,1}\rangle\). This also produces a state \(|E'_{1,1}\rangle = \Omega_2 |e'_1 g'_2\rangle - \Omega_1 |g'_1 e'_2\rangle) / \sqrt{\Omega^2_1 + \Omega^2_2} \). which is orthogonal to \(|E'_1\rangle\). Thus, the symmetric collective state (SCS), \(|E'_{1,1}\rangle\), does not remain isolated but is coupled to \(|E'_2\rangle\), which in turn is coupled to \(|E'_1\rangle\). Consider next the case where we also allow for potentially different detunings for the two atoms, \( \delta_1 \) and \( \delta_2 \). It is easy to see, based on the general definition in Equation (8) of the first excited SCS, that \(|E'_1\rangle\) has the same form as in Equation (8). Similarly, the expression for \(|E'_{1,1}\rangle\) is also the same as above, and these states are generated by the same rotation operator, \( R \), as given above. However, the coupling between the states in this rotated basis is now modified. Explicitly the ensemble \( Q \)-transformed Hamiltonian in the rotated frame becomes

\[
\tilde{H}'_C / \hbar = - (\delta_1 \Omega^2_1 + \delta_2 \Omega^2_2) (|E'_1\rangle \langle E'_1| + |E'_{1,1}\rangle \langle E'_{1,1}|) / (\Omega^2_1 + \Omega^2_2) \quad (9)
\]
Thus, the ACS \( |E'_{1,1}\rangle\) is now coupled directly to the SCS \(|E'_1\rangle\), in addition to being coupled to the state \(|E'_2\rangle\). Furthermore, the energies of the states are also shifted with respect to \(|G'\rangle\). These couplings and shifts are illustrated in Figure 3(b).

In an ensemble with a large number of atoms, the number of asymmetric states is far larger than that of the symmetric states. In the next section, we discuss a more generalized notion of asymmetric states is far larger than that of the symmetric states. In the next section, we discuss a more generalized view of collective states, considering the variations in different parameters and manifestations thereof in the behavior of the collective states.

In the preceding discussions, we have taken into account the fact that each atom is at a unique position (which means that it sees a unique phase of the laser), sees a potentially unique Rabi frequency, and is moving with a particular velocity which in turn produces a Doppler shift. A natural question that may arise is whether we are taking into account the fact that the position of each atom is changing with time, so that it would see a time varying Rabi frequency and laser phase. The temporal variation in Rabi frequency can be ignored because the velocity of each atom is assumed to be very small. In Appendix 1, we show that the temporal change in the laser phase seen by the atom is akin to taking into account the Doppler shift.

3. N-Atom ensemble

The Hamiltonian of an ensemble of \(N\) non-interacting and non-overlapping atoms is simply given by the sum of the Hamiltonians of the constituent atoms as noted above. It is convenient to express these as a sum of three parts: raising, lowering, and detuning: \(H'_r = H'_i + H'_l + H'_d\), where \(H'_r = \sum_{k=1}^{N} \hbar \omega_k |e'_k\rangle\langle g'_k| / 2, H'_l = \sum_{k=1}^{N} \hbar \omega_k |g'_k\rangle\langle e'_k| / 2, \) and \(H'_d = -\sum_{k=1}^{N} \hbar d_{k} |e'_k\rangle\langle e'_k|\). The raising part of the Hamiltonian, \(H'_r\) couples \(|E'_n\rangle\) to its adjacent higher SCS, \(|E'_{n+1}\rangle\).

Similarly, the lowering part of the Hamiltonian, \(H'_l\) couples \(|E'_n\rangle\) to its adjacent lower SCS, \(|E'_{n-1}\rangle\). The function of the third term, \(H'_d\) is twofold. First, it leads to a shift in the energy of the collective states (symmetric and asymmetric).

Second, under certain conditions, it leads to a coupling between the SCS and all the ACS’s, as well as among all the ACS’s, within the same manifold (i.e. the set of collective states corresponding to the absorption of a given number of photons). Analogous to Equation (8), \(|E'_{n+1}\rangle\) can be generated from \(|E'_n\rangle\), for any value of \(n\), using the following prescription

\[
|E'_{n+1}\rangle = \frac{H'_r |E'_n\rangle}{\sqrt{|E'_n\rangle|H'_r|E'_n\rangle}} \tag{11}
\]

To illustrate the use of Equation (11), we first consider the ideal case where each atom sees the same Rabi frequency, and experiences no Doppler shift, but still allowing for the fact that different atoms see different spatial phases. Since \(H'_d = 0\), the asymmetric states remain fully uncoupled from the symmetric states. Using Equation (11), we can now easily find \(|E'_1\rangle\), noting that \(|E'_0\rangle = |G'\rangle\). Application of \(H'_r\) to \(|G'\rangle\), upon normalization, then leads to the result that \(|E'_1\rangle = \sum_{k=1}^{N} |g'_k,g'_2,\ldots,e'_k,\ldots,g'_N\rangle / \sqrt{N}\). This is essentially the same as the well-known first-excitation Dicke state, with the exception that the spatial phases seen by the individual atoms are incorporated in the constituent states \(|g'_k\rangle\) and \(|e'_k\rangle\), as noted before in the context of \(N = 2\).

It is now easy to see how to generate \(|E'_1\rangle\) for any value of \(n\), by repeated application of \(H'_r\), and allowing for the normalization, as prescribed by Equation (11). Specifically,
we get
\[
|E_n^n| = J(N, n)^{-1/2} \sum_{k=1}^{J(N, n)} P_k \left| \mathcal{O}^{(N-n)} e^{\otimes n} \right|,
\]
where \( J(N, n) = J = \binom{N}{n} \), and \( P_k \) is the permutation operator \([34]\).

Under the ideal condition being considered here, the ACSs remain fully decoupled from the symmetric set at all times, as noted above. As such, an explicit description of the forms of the ACSs is not necessary for understanding the behavior of the ensemble. However, when we consider non-idealities later, it will be important to understand the form of the ACSs. Therefore, we discuss here how to determine these states explicitly in the ideal case, and a simple modification of this approach will then be used later on for the non-ideal cases, where the ACSs are relevant.

Consider a particular manifold corresponding to the absorption of \( n \) photons. The SCS is \(|E_n^n|\), and there are \((J-1)\) ACSs, denoted as \(|E_n^n|\) for \( j = 1 \) to \((J-1)\). To find these states, we consider \(\Phi_{N,n}\), the Hilbert subspace of dimension \( J \) spanned by the states \( P_k \left| \mathcal{O}^{(N-n)} e^{\otimes n} \right|\). The elements of \(\Phi_{N,n}\) are arbitrarily labeled \(\hat{s}_1, \hat{s}_2, \ldots, \hat{s}_{J}\). The SCS is a particular vector in this Hilbert space, and the ACSs are any set of mutually orthogonal vectors that are all normal to the SCS. Thus, the set of ACSs is not unique, and there are many ways to construct them. The standard procedure for finding such a set of orthonormal vectors is the Gram–Schmidt Orthogonalization (GSO) process. From a geometric point of view, the GSO process can be seen as a set of generalized rotations (with potentially complex angles) in the Hilbert space. Given that the SCS consists of a superposition of the basis vectors with real coefficients, these rotations can be viewed in terms of physical angles for \( N = 2 \) and 3, whereas for \( N > 3 \), the angles have to be interpreted in an abstract manner. In order to elucidate our understanding of the ACS’s, we first formulate the construction of ACS’s for arbitrary \( N \) and \( n \), by successive rotations of the Hilbert subspace, \(\Phi_{N,n}\). We then illustrate the application of this model for \( N = 3 \) for constructing some explicit version of the ACSs (noting that the \( N = 2 \) case has only a single ACS which can be found trivially and has been explained in detail in Section 2).

The elements of \(\Phi_{N,n}\), labeled \(\hat{s}_1, \hat{s}_2, \ldots, \hat{s}_{J}\), form the coordinate axes of this Hilbert space. In this picture, we can represent the SCS as \(\mathbf{V} = (\hat{s}_1 + \hat{s}_2 + \ldots + \hat{s}_J) / \sqrt{J}\), a vector that makes an angle, \(\theta = \cos^{-1}(1/\sqrt{J})\) with each of the axes. Thus, to find all the collective states of \(\Phi_{N,n}\), including the SCS and all the ACS’s, we proceed as follows. We start with the original set of coordinate axes: \(\hat{s}_1, \hat{s}_2, \ldots, \hat{s}_J\). We then carry out a set of \((J-1)\) rotations, producing a new set of coordinate axes that are mutually orthogonal. The rotation angles are chosen to ensure that after the \((J-1)\) rotations, one of the coordinate axes is parallel to \(\mathbf{V}\) (which is the SCS), so that the remaining set of coordinate axes can be identified as the ACSs. This is accomplished by carrying out the following steps:

**Step 1** We write \(\mathbf{V}\) as a sum of two terms, \(\mathbf{V}_{12}\) and \(\mathbf{V}_{\text{rest}}\), where \(\mathbf{V}_{12} = (\hat{s}_1 + \hat{s}_2) / \sqrt{J}\). Normalization of \(\mathbf{V}_{12}\) gives the unit vector \(\mathbf{V}_{12} = (\hat{s}_1 + \hat{s}_2) / \sqrt{2}\), revealing that it makes an angle \(\cos^{-1}(1/\sqrt{2})\) with \(\hat{s}_1\) and \(\hat{s}_2\). Therefore, the plane of \(\hat{s}_1\) and \(\hat{s}_2\) must be rotated around the origin by \(\theta_2 = (-\cos^{-1}(1/\sqrt{2}))\) to give \(\hat{s}_1' = (\hat{s}_1 - \hat{s}_2) / \sqrt{2}\) and \(\hat{s}_2' = (\hat{s}_1 + \hat{s}_2) / \sqrt{2}\). Obviously, \(\hat{s}_1'\) is parallel to \(\mathbf{V}_{12}\). By construction, \(\hat{s}_1'\) is orthogonal to \(\hat{s}_2'\), and therefore to \(\mathbf{V}_{12}\). Since \(\mathbf{V}_{\text{rest}}\) does not contain any component in the \((\hat{s}_1, \hat{s}_2)\) plane, it then follows that \(\hat{s}_1'\) is orthogonal to \(\mathbf{V}\), and is therefore an ACS. For \(N = 2\) described in Sec. 2, \(\hat{s}_1' = |E_{1,1}'\rangle\) and \(\hat{s}_2' = |E_{1,2}'\rangle\), and the process stops at this point.

**Step 2** The vector, \(\mathbf{V}\) is rewritten as another sum of two terms, \(\mathbf{V}_{123}\) and \(\mathbf{V}_{\text{rest}}\), where \(\mathbf{V}_{123} = (\hat{s}_1 + \hat{s}_2 + \hat{s}_3) / \sqrt{3}\). Normalization of \(\mathbf{V}_{123}\) gives the unit vector \(\mathbf{V}_{123} = (\hat{s}_1 + \hat{s}_2 + \hat{s}_3) / \sqrt{3}\), showing that it makes an angle \(\cos^{-1}(1/\sqrt{3})\) with \(\hat{s}_1, \hat{s}_2\) and \(\hat{s}_3\). Since \(\hat{s}_1'\) is orthogonal to \(\mathbf{V}\), we leave it undisturbed. The plane of \(\hat{s}_2'\) and \(\hat{s}_3'\) is rotated around the origin by \(\theta_3 = (-\cos^{-1}(1/\sqrt{3}))\), resulting in \(\hat{s}_2'' = (\hat{s}_1 + \hat{s}_2 - 2\hat{s}_3) / \sqrt{6}\) and \(\hat{s}_3'' = (\hat{s}_1 + \hat{s}_2 + \hat{s}_3) / \sqrt{3}\). It is clear that \(\hat{s}_2''\) is parallel to \(\mathbf{V}_{123}\). By construction, \(\hat{s}_2''\) is orthogonal to \(\hat{s}_1'\) and \(\hat{s}_3'\), and therefore, to \(\mathbf{V}_{123}\). Furthermore, since \(\mathbf{V}_{\text{rest}}\) does not contain any component in the \((\hat{s}_1, \hat{s}_2, \hat{s}_3)\) plane, it then follows that \(\hat{s}_2''\) is orthogonal to \(\mathbf{V}\). \(\hat{s}_2''\) is also orthogonal to \(\hat{s}_1',\) since it is a linear combination of \(\hat{s}_1'\) and \(\hat{s}_3'\), which are both orthogonal to \(\hat{s}_1'\). Thus, \(\hat{s}_2''\) is the second ACS. For \(N = 3\) and \(n = 2\), this is the terminal step, resulting in \(\hat{s}_1' = |E_{1,1}'\rangle\), \(\hat{s}_2'' = |E_{1,2}'\rangle\) and \(\hat{s}_3'' = |E_{1,3}'\rangle\), as shown in Figure 4.

**Step 3** \(\mathbf{V}\) is rewritten again as \(\mathbf{V} = \mathbf{V}_{1234} + \mathbf{V}_{\text{rest}}\), where \(\mathbf{V}_{1234} = (\hat{s}_1 + \hat{s}_2 + \hat{s}_3 + \hat{s}_4) / \sqrt{4}\). Again, normalizing \(\mathbf{V}_{1234}\) gives \(\mathbf{V}_{1234} = (\hat{s}_1 + \hat{s}_2 + \hat{s}_3 + \hat{s}_4) / \sqrt{4}\), showing that it makes an angle \(\cos^{-1}(1/\sqrt{4})\) with \(\hat{s}_1, \hat{s}_2, \hat{s}_3,\) and \(\hat{s}_4\). As described in Step 2 above, \(\hat{s}_1',\) and \(\hat{s}_2''\) are orthogonal to each other and to \(\mathbf{V}\), and, therefore, we leave these two undisturbed. To find the vector orthogonal to this pair as well as to \(\mathbf{V}\), we rotate the plane of \(\hat{s}_1''\) and \(\hat{s}_4\) about the origin by \(\theta_4 = \left(-\cos^{-1}\left(1/\sqrt{4}\right)\right)\), and derive \(\hat{s}_4'' = (\hat{s}_1 + \hat{s}_2 + \hat{s}_3 + 3\hat{s}_4) / \sqrt{12}\) and \(\hat{s}_4''' = (\hat{s}_1 + \hat{s}_2 + 3\hat{s}_3 + 4\hat{s}_4) / \sqrt{4}\). Following the same set of arguments presented in Step 2, it is easy to show that \(\hat{s}_4''\) is orthogonal to \(\hat{s}_1',\) \(\hat{s}_2''\) and \(\mathbf{V}\). As such, this is the third ACS. For \(N = 4\) and \(n = 1\), this is the terminal step, resulting in \(\hat{s}_1' = |E_{1,1}'\rangle\), \(\hat{s}_2'' = |E_{1,2}'\rangle\), \(\hat{s}_3''' = |E_{1,3}'\rangle\) and \(\hat{s}_4 = |E_{1,4}'\rangle\).
The vector, $\mathbf{S}$, at the Hilbert subspace $\Phi_1$ can be formalized by the method of matrix rotations considering the column vector formed by the elements of the space $\Phi_{N,n}$ as follows

$$\mathbf{S} = \begin{bmatrix} \hat{s}_1 & \hat{s}_2 & \cdots & \hat{s}_J \end{bmatrix}^T. \quad (13)$$

The vector, $\mathbf{S}$, undergoes a series of rotations that transforms it to another vector, $\mathbf{S}_C$, whose elements are the symmetric and asymmetric collective states for that particular manifold of the ensemble. The first rotation matrix, $R(2)$, causes a rotation of $\mathbf{S}$ in the $(\hat{s}_1, \hat{s}_2)$ plane to form $\mathbf{S}_2$ whose elements are $\left\{ \hat{s}'_1, \hat{s}'_2, \hat{s}_3, \ldots, \hat{s}_J \right\}$. The second rotation matrix, $R(3)$, further rotates the vector $\mathbf{S}_2$ in the $(\hat{s}_2, \hat{s}_3)$ plane to give $\mathbf{S}_3$. This process is continued until the vector, $\mathbf{S}_J \equiv \mathbf{S}_C$, is formed by applying $R(J)$ on $\mathbf{S}_{J-1}$. Therefore, the overall process may be expressed as $\mathbf{S}_C = R_T \mathbf{S}$, where $R_T = R(J)R(J-1) \ldots R(3)R(2)$. The $j$-th rotation vector is of the form

$$R(j)_{m,n} = \begin{cases} 1 & \text{for } m = n, m \neq j - 1, j \\ \cos \theta_j & \text{for } m = n = j - 1, j \\ -\sin \theta_j & \text{for } m = j, n = j - 1 \\ \sin \theta_j & \text{for } m = j - 1, n = j \\ 0 & \text{otherwise} \end{cases} \quad (14)$$

where $\theta_j = \cos^{-1}(1/\sqrt{j})$, so that $\cos \theta_j = 1/\sqrt{j}$ and $\sin \theta_j = \sqrt{(j-1)/j}$. This matrix represents a simple rotation by an angle of $(-\theta_j)$ in the plane of $\hat{s}'_{j-1}$ and $\hat{s}_j$. To visualize this, we show below the explicit form of $R(2)$, $R(3)$, and $R(4)$.

$$R(2) = \begin{bmatrix} \cos \theta_2 & -\sin \theta_2 & 0 & 0 & \cdots & 0 \\ \sin \theta_2 & \cos \theta_2 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \end{bmatrix}$$

$$\theta_2 = \cos^{-1}(1/\sqrt{2}),$$

$$R(3) = \begin{bmatrix} 1 & 0 & 0 & 0 & \cdots & 0 \\ 0 & \cos \theta_3 & -\sin \theta_3 & 0 & \cdots & 0 \\ 0 & \sin \theta_3 & \cos \theta_3 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \end{bmatrix}$$

$$\theta_3 = \cos^{-1}(1/\sqrt{3}),$$

$$R(4) = \begin{bmatrix} 1 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 0 & \cos \theta_4 & -\sin \theta_4 & \cdots & 0 \\ 0 & 0 & \sin \theta_4 & \cos \theta_4 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \end{bmatrix}$$

$$\theta_4 = \cos^{-1}(1/\sqrt{4}). \quad (15)$$

In general, for arbitrary $N$, $n$ and therefore $J$, the SCS, and ACSs can be expressed as follows

$$|E'_n\rangle = \sum_{l=1}^J \hat{s}_l / \sqrt{J},$$

$$|E'_{n,j}\rangle = \left( \sum_{l=1}^j \hat{s}_l - j \hat{s}_{j+1} \right) / \sqrt{j(j+1)}, \quad (16)$$

where $j = 1, 2, \ldots, n-1$. Conversely, the original unrotated vectors can be written in terms of the rotated, collective states bases as follows.

\[ \text{Figure 4. Hilbert subspace rotation of the first excited state of an ensemble of three atoms.} \]
\[ \hat{s}_j = \frac{|E'_n|}{\sqrt{J}} + \sum_{i=1}^{J-1} \left| E'_{n,i} \right| \sqrt{J(j+1)}, \]
\[ \hat{s}_j = \frac{|E'_n|}{\sqrt{J}} + \sum_{i=j}^{J-1} \left| E'_{n,i} \right| \sqrt{J(j+1)} \]
where \( j = 2, \ldots, n-1 \). This inversion is useful in illustrating the behavior of the collective states in more complex situations, an example of which will be presented shortly.

In order to get a clearer picture of how the spread in detuning affects the behavior of the ensemble, consider the simple case of a three-atom ensemble interacting with a laser of uniform profile. Additionally, we assume that the \( i \)-th atom experiences a detuning of \( \delta_i \). The manifold corresponding to \( 1 \) photon is spanned by the set \( \Phi_{3,1} \), whose elements, given by \( |e'_1g'_2g'_3\rangle, |g'_1e'_2g'_3\rangle, \) and \( |g'_1g'_2e'_3\rangle \), are now labeled as \( s_1, \delta_2, \) and \( s_3 \), respectively. The SCS of this manifold, as defined in Equation (16), is given by \( |E'_{1,1}\rangle = (s_1 + \sqrt{3})/\sqrt{3} = (|e'_1g'_2g'_3\rangle + |g'_1e'_2g'_3\rangle + |g'_1g'_2e'_3\rangle)/\sqrt{3} \). One of the possible ways of forming the set of ACSs is \( |E'_{1,2}\rangle = (s_1 - \sqrt{3})/\sqrt{3} = (|e'_1g'_2g'_3\rangle - |g'_1g'_2e'_3\rangle)/\sqrt{3} \). The action of the ensemble Hamiltonian, \( H' = H'_c + H'_r + H'_s \) on \( |E'_{1}\rangle \), shows how it experiences an energy shift, and couples with its adjacent states as follows:

\[ H'_c \mid E'_{1}\rangle /\hbar = \Omega (|e'_1g'_2g'_3\rangle + |g'_1e'_2g'_3\rangle + |g'_1g'_2e'_3\rangle)/\sqrt{3}, \]
\[ H'_r \mid E'_{1}\rangle /\hbar = \sqrt{3} \Omega |g'_1g'_2g'_3\rangle /2. \]
\[ H'_s \mid E'_{1}\rangle /\hbar = -\delta \left( g'_1g'_2g'_3 \right)/\sqrt{3}. \]

It can be seen from Equation (16) that Equation (18a) can be written as \( H'_c \mid E'_{1}\rangle /\hbar = \Omega \mid E'_{2}\rangle \) and Equation (18b) can be written as \( H'_r \mid E'_{1}\rangle /\hbar = \sqrt{3} \Omega \mid G'\rangle /2 \). Furthermore, each term on the right-hand side in Equation (18c) can be written in terms of the relevant SCS and ACSs according to Equation (17):

\[ H'_r \mid E'_{1}\rangle /\hbar = -\delta \hat{s}_1/\sqrt{3} - \delta_2 \hat{s}_2/\sqrt{3} - \delta_3 \hat{s}_3/\sqrt{3} \]
\[ = -\left( \delta_1 + \delta_2 + \delta_3 \right) /\sqrt{3} \]
\[ - \left( \delta_1 + \delta_2 - 2\delta_3 \right) /\sqrt{3}. \]

In the more complex case where each atom in the ensemble experiences a unique Rabi frequency, the raising part of the ensemble Hamiltonian applied to any SCS yields the next higher SCS of that ensemble, as prescribed in Equation (11). To illustrate this, consider the example of a four-atom ensemble where the raising part of the Hamiltonian is \( H'_r = \sum_{i=1}^{4} h \Omega_i |e'_i \rangle \langle g'_i| /2 \). The set of SCSs are therefore, the following:

\[ |E'_{1}\rangle = (\Omega_1 |e'_1g'_2g'_3\rangle + \Omega_2 |g'_1e'_2g'_3\rangle + \Omega_3 |g'_1g'_2e'_3\rangle + \Omega_4 |e'_1g'_2g'_3\rangle) \times (\Omega_1^2 + \Omega_2^2 + \Omega_3^2 + \Omega_4^2)^{-1/2} \]
\[ |E'_{2}\rangle = (\Omega_1 \Omega_2 |e'_1g'_2g'_3\rangle + \Omega_2 \Omega_3 |g'_1e'_2g'_3\rangle + \Omega_2 \Omega_4 |g'_1g'_2e'_3\rangle + \Omega_1 \Omega_3 |g'_1g'_2e'_3\rangle + \Omega_1 \Omega_4 |g'_1g'_2g'_3\rangle)((\Omega_1^2 \Omega_2^2)^{-1/2} \]
\[ |E'_{3}\rangle = (\Omega_1 \Omega_2 \Omega_3 |e'_1g'_2g'_3\rangle + \Omega_1 \Omega_2 \Omega_4 |e'_1g'_2g'_3\rangle + \Omega_1 \Omega_3 \Omega_4 |g'_1g'_2e'_3\rangle + \Omega_1 \Omega_3 \Omega_2 |e'_1g'_2g'_3\rangle + \Omega_1 \Omega_3 \Omega_2 |g'_1g'_2e'_3\rangle + \Omega_1 \Omega_3 \Omega_4 |g'_1g'_2g'_3\rangle)^{-1/2} \]
\[ |E'_{4}\rangle = |e'_1g'_2g'_3\rangle. \]

The set of ACSs corresponding to \( |E'_{n}\rangle \) in the present case of non-uniform Rabi frequency consists of \( (J-1) \) elements that are orthogonal to one another as well as to \( |E'_{n}\rangle \). As mentioned above, they can be constructed using the GSO process. The realization of this process as a set of rotations follows a similar set of rules as described above. However, the rotation angles will now depend on the relative amplitudes of all the Rabi frequencies. The details of this process are beyond the scope of the present discussion and will be presented elsewhere.

4. Quantized COM model of ensemble

As mentioned earlier, we have been investigating the use of atomic ensembles for a COSAIN. In a CRAIN, one must take into account the quantum nature of the COM motion. Similarly, for a COSAIN, we must consider the COM motion of the atom quantum mechanically. In doing so, one must consider all the degrees of freedom of the COM. However, for a CRAIN as well as the COSAIN (which is a variant of the CRAIN), only the motion in the direction parallel to the laser beams (which we have chosen to be the \( z \) direction) has to be quantized. As such, in what follows, we keep our discussion confined to such a scenario.

The \( i \)-th atom is now a Gaussian wave packet formed by the superposition of an infinite number of plane waves, where the \( p \)-th plane wave can exist in two energy states, \( |g_{ip}, h k'_p\rangle \) and \( |e_{ip}, h (k'_p + k)\rangle \), which differ by a momentum \( h k \). Since the laser field amplitude is assumed to be
constant in the \( z \) direction, the Rabi frequency experienced by each plane wave manifold of the \( i \)-th atom is \( \Omega_i \). The Doppler shift induced due to the thermal motion of the atoms in the \( z \) direction ascribes a detuning of \( \delta \tau_i \) to this atom. As such, the Hamiltonian of the \( p \)-th plane wave of the \( i \)-th atom is

\[
\begin{align*}
H_{ip} &= \left( \omega_e + \hbar k_{ip}^2 / 2m \right) |g_{ip}\rangle \langle g_{ip}| \\
&+ \left( \omega_e + \hbar (k_{ip}^2 + k^2) / 2m \right) |e_{ip}\rangle \langle e_{ip}| \\
&+ \Omega_i \left( \exp \left( i \left( \omega_{0i} t - \xi_i \right) \right) \right) |g_{ip}\rangle \langle e_{ip}| + h.c. \right) / 2.
\end{align*}
\]

The Schrödinger equation governing the evolution of the state vector of this plane wave, \( \psi_{ip} \), is

\[
i \hbar \dot{\psi}_{ip} / \dot{t} = H_{ip} \psi_{ip}.
\]

Similar to the description given in Equations (3) and (4), a unitary transformation, \( Q_{ip} \), changes \( \psi_{ip} \) to \( \psi'_{ip} \) such that

\[
Q_{ip} = \sum_{j=1}^{2} \exp \left( i (a_{ip} t + b_{ip}) j \right) \langle j | j \rangle,
\]

where \( a_{ip} \) and \( b_{ip} \) are the arbitrary parameters. The Hamiltonian in the new basis vector thus formed is \( H'_{ip} = Q_{ip} H_{ip} Q_{ip}^{-1} + i \hbar \dot{Q}_{ip} Q_{ip}^{-1} \), so that

\[
i \hbar \dot{\psi}'_{ip} / \dot{t} = H'_{ip} \psi'_{ip}.
\]

It can be stripped of its time dependence by setting \( a_{ip1} = \omega_e + \hbar k_{ip}^2 / 2m \) and \( a_{ip2} = \omega_e + \delta_{ei} + \hbar k_{ip}^2 / 2m \). For \( b_{ip1} = 0 \) and \( b_{ip2} = -\xi_i \), \( H'_{ip} \) is rendered independent of any phase factors. In the transformed frame, the Hamiltonian is thus

\[
H'_{ip} / \hbar = \left( -\delta_{ei} + \hbar k^2 / 2m + \hbar k k_{ip}^2 / m \right) \langle e'_{ip} | e'_{ip} \rangle \\
+ \Omega_i \left( \langle g'_{ip} | e'_{ip} \rangle + h.c. \right) / 2.
\]

Since the atom is a sum of these individual plane waves, it evolves according to the equation that is the sum of the individual Schrödinger equations, \( i \hbar \partial (\sum_{p=-\infty}^{\infty} \psi'_{ip}) / \partial t = \sum_{p=-\infty}^{\infty} H'_{ip} \psi'_{ip} \). In the limit that the Rabi frequency of the \( i \)-th atom is large compared to the Doppler shift due to the COM momentum of each of the constituent plane waves, i.e. \( \Omega_i \gg \hbar k k_{ip}^2 / m \), the corresponding Hamiltonians become identical to one another. The resulting evolution equation is then

\[
i \hbar \dot{\psi}'_{ip} / \dot{t} = H'_{ip} \psi'_{ip}, \quad \text{where } |\psi'_{ip}\rangle = \sum_{p=-\infty}^{\infty} \langle \psi'_{ip} | \psi'_{ip} \rangle \psi'_{ip}.
\]

This is identical to the semiclassical Hamiltonian of the atom where the COM mass degree of freedom of the atom is not considered. Thus, we conclude that, under approximations that are valid for the COSAIN, a semiclassical description of the COM motion of each atom is sufficient. As such, all the results we have derived above regarding the properties of collective state remain valid for the COSAIN.

5. Summary

We have investigated the behavior of an ensemble of \( N \) non-interacting, identical atoms excited by a laser with a wavelength of \( \lambda \). In doing so, we have assumed that the wave functions of the atoms do not overlap with one another, so that quantum statistical properties are not relevant. In general, the \( i \)-th atom sees a Rabi frequency \( \Omega_i \), an initial phase dependent laser phase \( \phi_i \), and a motion induced Doppler shift of \( \delta \). When \( \Omega_i = \Omega \) and \( \delta = \delta_i = 0 \) for all atoms, the system evolves into a superposition of \( (N+1) \) generalized symmetric collective states, independent of the values of \( \phi_i \). If \( \phi_i = \phi \) for all atoms, these states simplify to the well-known Dicke collective states. When \( \Omega_i \) or \( \delta_i \) is distinct for each atom, the system evolves into a superposition of symmetric as well as asymmetric collective states. For large values of \( N \), the number of asymmetric states \( (2^N - (N+1)) \) is far larger than that of the symmetric states. For a COSAIN and a COSAC, it is important to understand the behavior of all the collective states under various conditions. In this paper, we have shown how to formulate systematically the properties of all the collective states under various non-idealities, and used this formulation to understand the dynamics thereof. Specifically, for the case where \( \Omega_i = \Omega \) and \( \delta_i = 0 \) for all atoms, we have shown how the amplitudes of each of the generalized collective states can be determined explicitly in a simple manner. For the case where \( \Omega_i \) or \( \delta_i \) is distinct for each atom, we have shown how the symmetric and asymmetric collective states can be treated on the same footing. Furthermore, we have shown that the collective states corresponding to the absorption of a given number of photons can be visualized as an abstract, multi-dimensional rotation in the Hilbert space spanned by the ordered product states of individual atoms. This technique enables one to construct the explicit expression for any asymmetric state of interest. Such
expressions in turn can be used to determine the evolution of such a state in the COSAIN or the COSAC. We have also considered the effect of treating the COM degree of freedom of the atoms quantum mechanically on the description of the collective states. This is particularly relevant for the COSAIN. In particular, we have shown that it is indeed possible to construct a generalized collective state when each atom is assumed to be in a localized wave packet.

**Appendix 1. Equivalence between Doppler effect induced phase shift and position change induced phase shift**
Consider an ideal two-level atom excited by a laser field traveling in the z direction, assuming the field amplitude to be uniform in all directions. The atom is modeled as having two energy levels, |g⟩ and |e⟩. For the issue at hand, it is not necessary to consider the radiative decay of |e⟩. As such, we assume both of the states to be long-lived. This two-level system is shown in Figure A1(a), where ω0|g⟩ is the frequency of the laser field, assumed to be resonant for a stationary atom. The laser field is assumed to be polarized, arbitrarily, in the x direction. As illustrated in Figure A1(b), the atom is initially (t = 0) positioned at r0 = z0|g⟩ + y0|e⟩ and is moving in the z direction with a non-relativistic velocity v. The electric field at a time t in the atom’s frame of reference is E(t, t) = SEβ cos(ω0t − kz), where z = z0 + vt. In the semiclassical model employed here, the Hamiltonian of this atom can be written as 

\[ H = \hbar \omega_g |g⟩⟨g| + \hbar \omega_e |e⟩⟨e| + Ω \exp(i(ω_0t − k(z_0 + vt))) |g⟩⟨g| + 2H_c, \]

where Ω ≡ |⟨g| (x · ρ) |e⟩ E/h| = |⟨e| (x · ρ) |g⟩ E/h|. The state of this atom, |ψ⟩, evolves according to the Schrödinger equation, iℏ ∂̂ψ/∂t = H ̂|ψ⟩. A unitary transformation, Q, defined as Q ≡ \[ \sum_{j=1}^{2} \exp(i(a_j z + b_j y)) |j⟩⟨j| \] changes |ψ⟩ to |ψ’⟩ = Q|ψ⟩, where a_j and b_j are the arbitrary parameters. The Q-transformed Hamiltonian for this state vector is then H’ = QH Q^{-1} − hQ Q^{-1}, so that iℏ ∂̂ψ’/∂t = H’ ̂|ψ’⟩. H’ is stripped of its time dependence by setting a_1 = ω_g and a_2 = ω_0 + ω_g = ω_e − kv. Now, setting b_1 = 0, b_2 = −kz_0 makes H’ independent
of any phase factor as well. The $Q$-transformed Hamiltonian thus becomes

$$H' = kv |e'\rangle\langle e'| + \Omega (|g'\rangle\langle e'| + h.c.)/2.$$  \hspace{1cm} \text{(A2)}

We consider this atom’s interaction with two consecutive laser fields separated by a dark zone of duration $T$, as illustrated in Figure A1(c). The time of interaction of the atom with each field is such that $\tau = \pi/2\Omega$. The atom initially at $z = z_0$ drifts to $z = z_0 + kv t$ by the end of the entire interaction sequence. For the sake of simplicity, we assume that $kv \ll \Omega$ and that the atom’s position does not change appreciably over the duration of the pulse. The new basis vectors, $|g'\rangle$ and $|e'\rangle$, are related to the original basis vectors as $\exp(-i\omega_0 t) |g\rangle$ and $\exp(-i(\omega_0 - kv)t - k z_0) |e\rangle$, respectively. If the atom is initially in $c_{g}(0) |g'\rangle + c_{f}(0) |e'\rangle$, its state after interaction for a time $t$ is given by Equation (5).

The Hamiltonian for the second pulse will be $H_{L2}/h = \omega_0 |g\rangle\langle g| + \omega_e |e\rangle\langle e| + \Omega (|g\rangle\langle e| + |e\rangle\langle g|)/2$. The result of $Q$-transformed Hamiltonian in the bases of $|g'\rangle_L$ and $|e'\rangle_L$ is $H'_{L}/h = \Omega (|g'\rangle\langle e'| + h.c.)/2$. As a result, considering that the atom is in state $|g'\rangle_L$ at $t = 0$, the state of the atom at $t = \tau$ is $|\psi'\rangle = (|g'\rangle_L - i |e'\rangle_L)/\sqrt{2}$. The dark zone $Q$-transformed Hamiltonian, $H'_{L2}$, contains no non-zero elements. Thus, the state of the atom is $|\psi'\rangle = (|g'\rangle_L - i |e'\rangle_L)/\sqrt{2}$.

After the atom’s encounter with the second pulse ($t = 2\tau + T$), its quantum state can be written as $|\psi_2\rangle = (1 - \exp(-i k v T)) |g\rangle_L/2 - i(1 + \exp(-i k v T)) |e\rangle_L/2$. In the original bases of $|g\rangle$ and $|e\rangle$, the final state of the atom at the end of the separated field interaction sequence is given by

$$|\psi_2\rangle = (1 - \exp(-i k v T)) \exp(-i \omega_0 t) |g\rangle_L/2 - i(1 + \exp(-i k v T)) \exp(-i \omega_0 - k v) t + i k z_0) |e\rangle_L/2.$$

Now, we consider the same interaction shown in Figure A1(c) in the laboratory frame of reference in which the electric field at any point along the laser’s propagation direction is given by $E(r, t) = \tilde{E} \cos(\omega_0 t - k z)$. Considering that at $t = 0$, the atom is positioned at $z = z_0$, the Hamiltonian for the first interaction zone is given by $H_{L1}/h = \omega_0 |g\rangle\langle g| + \omega_e |e\rangle\langle e| + \Omega (\exp(i(\omega_0 t - k z_0)) |g\rangle_{L1}\langle e| + h.c.)/2$, where the subscript $L$ indicates that this is in the laboratory frame. The state of the atom evolves according to $i\hbar \partial |\psi_L\rangle/\partial t = H_{L1} |\psi_L\rangle$. Therefore, the transformation $Q_1$ to remove time and phase dependence from $H_{L1}/h$ is given by $Q_1 = \exp(i\omega_0 t) |1\rangle\langle 1| + \exp(i(\omega_0 t - k z_0)) |2\rangle\langle 2|$. The resulting $Q$-transformed Hamiltonian in the bases of $|g'\rangle_L$ and $|e'\rangle_L$ is $H'_{L1}/h = \Omega (|g'\rangle\langle e'| + h.c.)/2$. As a result, considering that the atom is in state $|g'\rangle_L$ at $t = 0$, the state of the atom at $t = \tau$ is $|\psi'\rangle = (|g'\rangle_L - i |e'\rangle_L)/\sqrt{2}$. The dark zone $Q$-transformed Hamiltonian, $H'_{L2}$, contains no non-zero elements. Thus, at the end of the dark zone ($t = \tau + T$), the quantum state of the atom remains unaltered. Since the atom has a non-zero velocity, $v$ along $z$ direction, by the end of the dark zone, it will have moved to $z = z_0 + kv$. As a consequence, the Hamiltonian for the second pulse will be $H_{L2}/h = \omega_0 |g\rangle\langle g| + \omega_e |e\rangle\langle e| + \Omega (\exp(i(\omega_0 t - k z_0)) |g\rangle_{L2}\langle e| + h.c.)/2$. The $Q$-transformation required to make $H_{L2}$ time and phase factor independent may be written as $Q_2 = \exp(i\omega_0 t) |1\rangle\langle 1| + \exp(i(\omega_0 t - k z_0)) |2\rangle\langle 2|$. We define $|\psi''\rangle_L = Q_2 |\psi_L\rangle$. The new basis states thus formed are $|g''\rangle_L = \exp(i\omega_0 t) |g\rangle_L$ and $|e''\rangle_L = \exp(i\omega_0 t - k z_0) |e\rangle_L$. Therefore, the quantum state of the atom at the end of the dark zone ($t = \tau + T$), must now be written in the $Q_2$-transformed bases of $|g''\rangle_L$ and $|e''\rangle_L$. As such, we get $|\psi''\rangle_L = Q_2 Q_1^{-1} |\psi'\rangle_L = (|g''\rangle_L - i \exp(ik(z_0 - z_0))|e''\rangle_L)/\sqrt{2}$. This is the initial condition for the second pulse. At the end of the second pulse, $t = 2\tau + T$, the atom’s quantum state is, therefore, given by $|\psi''\rangle_L = (1 - \exp(ik(z_0 - z_0)) |g''\rangle_L/2 - i(1 + \exp(ik(z_0 - z_0)) |e''\rangle_L/2$. Thus, in the original bases of $|g\rangle_L$ and $|e\rangle_L$, the state of the atom is

$$|\psi_2\rangle = (1 - \exp(ik(z_0 - z_0)) \exp(-i \omega_0 t) |g\rangle_L/2 - i(1 + \exp(ik(z_0 - z_0)) \times \exp(-i \omega_0 + k z_0) |e\rangle_L/2.$$

Since $z_0 = z_0 + v T$, Equation (A5) is identical to Equation (A4). Thus, when one takes into account the Doppler shift, it is no longer necessary to consider explicitly the fact that the atom sees a different laser phase at different times.
